## Topology options for deploying NFV

“[NFV](#) aims to transform the way that network operators architect networks by evolving standard IT [virtualization](#) technology to consolidate many network equipment types onto industry-standard high-volume servers, switches and storage, which **could be located in data centers, network [nodes](#), and in the end-user premises.**”

According to **ETSI – NFV** (a priori solutions)

1. Centralized NFV Topology
2. Service Edge NFV Topology

## Advantages

- OPEX (i.e. deployment and cooling costs) for implementing each virtual service is **low**, and re-use of **resources is maximized**.
- Compute and storage **resources can easily be added** to the centralized location.

## Disadvantages

- No support of services where particular functionality is needed at the service edge
  - e.g. - **the most effective DDoS defense scheme** is to block attack traffic close to the source [1]
  - e.g. - **latency-sensitive applications**, deploying 5G networks where network functions are the most sensitive to latency, thus they need to be located as close as possible to end-user devices

## Centralized NFV Topology

[1] T. Peng et al. - ACM Computing Surveys, Vol. 39, No. 1, Article 3, Publication date: April 2007

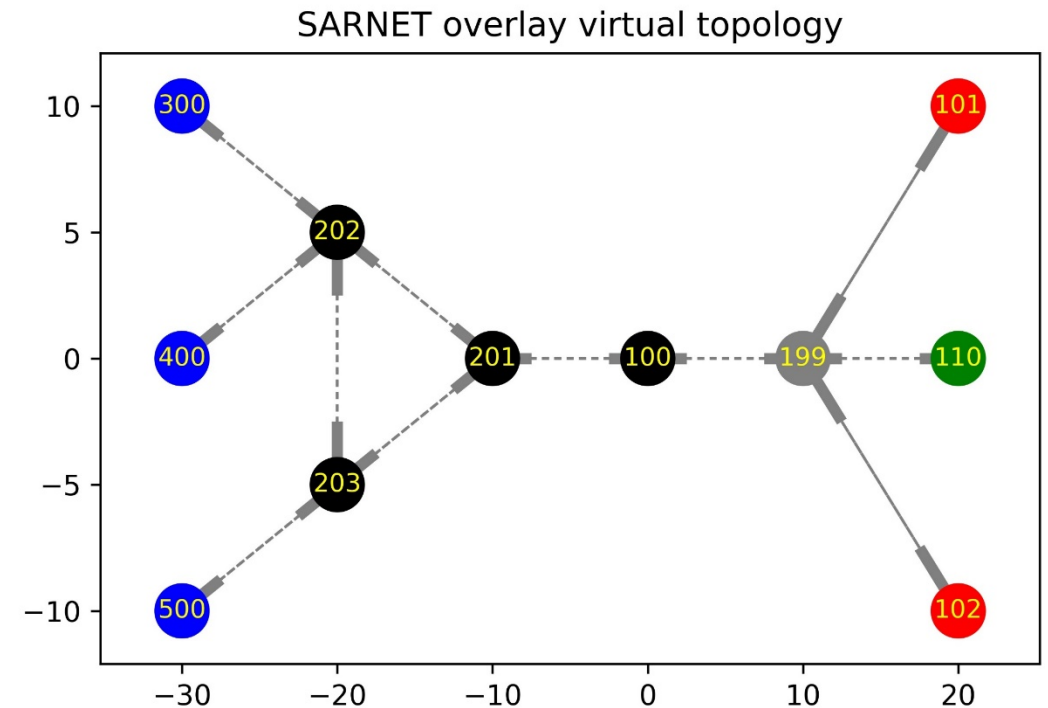

## Service Edge NFV Topology

### Advantages

- Enables services that are not possible to deploy in a centralized model
  - e.g. - effective **security defense schemes** at the edge for DDoS
  - e.g. - **latency-sensitive applications**

### Disadvantages

- Ability to **add additional services or scale is limited** by the installed resources - this limitation is overcome using a chained approach

## Chained NFV Topology

### Advantages

- One advantage of the chained model over the service edge model is the **ability to add virtualization resources** without having to upgrade the service edge.
- The chained model can **support all of the advanced applications** that are **available with the service edge model**.

### Disadvantages

- Requires **advanced orchestration** to combine physical and virtual resources

## On going research...

### Main Tasks

To design a **topology-aware heuristic algorithm** to efficiently allocate VNFs in a NFV/SDN environment

### Specifics

1. Modeling of the **network function placement and chaining problem** by means of an ILP model, taking into account the topology awareness (i.e. for a given infrastructure) – for small networks size and service demands.
2. Designing an **heuristic algorithm** to efficiently place the VNFs for a specific scenario (i.e. DDoS, load balancing, etc).
3. Evaluating the **results of the proposed solution with the results obtained using an optimal placement** (i.e. ILP model).
4. Determining **network metrics and parameters** to compare the results of the heuristic algorithm against other topology option (i.e. centralized and service edge NFV topology).

## Modeling **network function placement** and **chaining problem** (1/3)

PHYSICAL NETWORKS --> infrastructure

$\_P$  is used to denote whether variables refers to physical resources.

$G = (N, E)$  --> unidirectional network graph (cloud infrastructure, physical network, etc...)

$N\_P [n]$ : network nodes

$E\_P [i, j]$ : network links for  $(i, j)$  in  $E$

$C\_P [n]$ : CPU capacity in % of each node ( $n$  in  $N$ )

$B\_P [i,j]$ : Bandwidth capacity of each  $(i,j)$  in  $E$

$D\_P [i,j]$ : Delay of each  $(i,j)$  in  $E$

## Modeling **network function placement** and **chaining problem** (2/3)

### NETWORK FUNCTIONS

$F$  [f]: denote the set of possible VNFs that may be instantiated/placed in the infrastructure.

$U$  [f]: denote the number of times that each network function can be instantiated, due to licensing purchases.

$F_{\text{CPU}}$  [f, inst]: each instance (inst in  $U$ ) provides a limited amount of resources to process demands. This enables our model to represent instances of the same VNF with different capabilities.

$F_{\text{DELAY}}$  [f]: each function (f in  $F$ ) has a processing delay associated to it.

## Modeling **network function placement** and **chaining problem** (3/3)

SERVICE FUNCTION CHAININGS (SFCs) --> VNFs requests

$\_S$  is used to denote whether variables refers to demand of services.

$S [q]$ : denote the set of service functions chains ( $q$  in  $S$ ).

$E\_S [k,l]$ : virtual edge ( $k,l$ ) between functions requested in the service chain  $k$ , represent the topology of the SFCs

$C\_S [k, f]$ : CPU capacity required by function  $f$  in chain  $k$

$B\_S [k,l]$ : Bandwidth requested for each virtual edge ( $k,l$ ) in  $E\_S$       $D\_S [k,l]$ : Delay requested for each virtual edge ( $k,l$ ) in  $E\_S$
